**ABSTRACT:** Anaplasmosis is a disease caused by obligate gram-negative intracellular bacteria. *Anaplasma* in cats is generally infected by *Anaplasma phagocytophilum*, however there are very limited reports of *Anaplasma bovis* such as *Anaplasma marginale* and *Anaplasma centrale* being reported to infect cats. This is the first report of anaplasmosis caused by *Anaplasma centrale* in cats. The owner brought a one-year-old female domestic cat to the Animal Hospital of Hasanuddin University in Makassar with the condition of not wanting to eat, weak, lethargic, dehydrated, and not defaecating. Diagnosis is carried out through anamnesis, physical examination, clinical examination, and laboratory examination, in the form of haematology and blood smear tests. The results of the examination revealed flea infestation, a blood test identified *Anaplasma centrale* with characteristics such as the presence of morulae in the middle part of the erythrocytes, and routine blood work showed anaemia which was seen in the MCV parameters increasing and the MCHC values decreased. Treatment consists of administration of antibiotics, anti-inflammatory drugs, and supportive therapy. The cat showed good results, with symptoms starting to disappear and the animal appeared active.

**Keywords:** Anaplasmosis, *Anaplasma bovis*, *Anaplasma centrale*, domestic cat

**INTRODUCTION**

Anaplasmosis is a disease caused by one of two gram-negative obligate intracellular bacterial agents, *Anaplasma phagocytophilum*, with the characteristic presence of intracytoplasmic morulae in white blood cells. The main vector of *Anaplasma phagocytophilum* is ticks from the genus *Ixodes*, namely the *Ixodes ricinus* and *Ixodes persulcatus* complex (Sykes 2013). Detection of anaplasmosis in animals can generally be performed through blood smear tests until PCR (Gorna et al. 2013). Clinical signs visible during physical examination in cats include fever, lethargy, tachypnoea, ataxia, hyperesthesia, muscle and joint pain, lameness, conjunctivitis, and ocular discharge (Sykes 2013). The condition of fleas and long hair on an animal's body can increase the degree of tick infestation because damp conditions provide a favourable environment for ticks (Arsyitahlia et al. 2021).

Anaplasmosis in cats is generally caused by *Anaplasma phagocytophilum*, however there are very limited reports of *Anaplasma bovis* such as *Anaplasma marginale* and *Anaplasma centrale* being reported to infect cats. There are only a few reports on the occurrence of *Anaplasma centrale* in Felidae wildlife in Africa (Makgabo et al. 2023), and this was also reported in a limited number of samples (Oliveira et al. 2018, André 2018). Reports of anaplasmosis in cats in Indonesia are also difficult to find, and there are only reports in dogs (Wardani et al. 2023). This study is the first to report the incidence of *Anaplasma centrale* in cats and the treatment carried out at the Animal Hospital of Hasanuddin University, Makassar.

**CASE**

**Signalement:** Domestic cat, female, 1 year old, weight 3.9 kg. The cat did not want to eat, was weak, lethargic, dehydrated, and had not defaecated a day before (Figure 1A).

**Anamnesis:** The cat has been kept since the age of 3 months. The cats were kept in-house. Deworming medications and vaccines were administered.

**Physical Examination:** The results of the physical examination are shown in Table 1.

**Haematology:** The cat had anaemia, characterised by a decrease in MCHC because the body had lost a lot of blood cells. MCV increases because of the larger size of the red blood cells.

**Blood Smear:** A blood smear found a round dot in the middle of the erythrocyte cell (Figure 1B).

**Figure 1.** Cat conditions and blood smear test results. (A) The condition of a cat infected with *Anaplasma centrale* and (B) intracytoplasmic inclusions (arrow) at the centre of the erythrocyte body as *Anaplasma centrale* at 1000x magnification with Giemsa staining.

The antibiotic doxycycline was used because it is capable of intracellular penetration and is bacteriostatic (Yancey et al. 2018). Meloxicam® inhibits the formation of inflammatory mediator prostaglandins (Priyanka et al. 2017). Sangobion® supports iron as an important mineral for the production of RBCs. Ringer Lactate® infusion combined with Neurosan® to restore body fluids and help the formation of red blood cells and nerves. Curcumal®, Gold-G®, and Imboost® have been used to increase immunity (Putra et al. 2019). Treatment showed good results, and on the third day, the symptoms began to disappear, the animal looked active, and was given outpatient care.

### CONCLUSION

Cats were infected with *Anaplasma centrale* based on blood smear findings showing intracytoplasmic inclusions in the middle of the erythrocyte bodies.
